Capital Cost of Low Carbon Hydrogen: Postcombustion Blue H₂ as an Example

Basis: Precombustion amine capture from Hydrogen. Total capital cost categorized by equipment cost to yield approximate cost per category.

Capital Cost of Low Carbon Hydrogen: Ultimate Destination

- Enhanced Oil Recovery can justify (varies with geology, geography, and oil price)
- Shared pipeline systems bring economies of scale
- Carbon Utilization initiatives seek opportunities to turn cost to value
- Geologic research has identified widespread storage opportunities

Capital Cost of Low Carbon Hydrogen: Compression

- Capture technology can somewhat affect suction pressure...but high discharge pressures set by geology and hydraulics.
- Some carbon utilization targets do not require compression

Capital Cost of Low Carbon Hydrogen: Support

- Carbon capture systems can be large users of steam, power, and cooling
- Fortunately, hydrogen plants often export steam and have other utilities available, minimizing new utility capital requirements

Capital Cost of Low Carbon Hydrogen: Carbon Capture

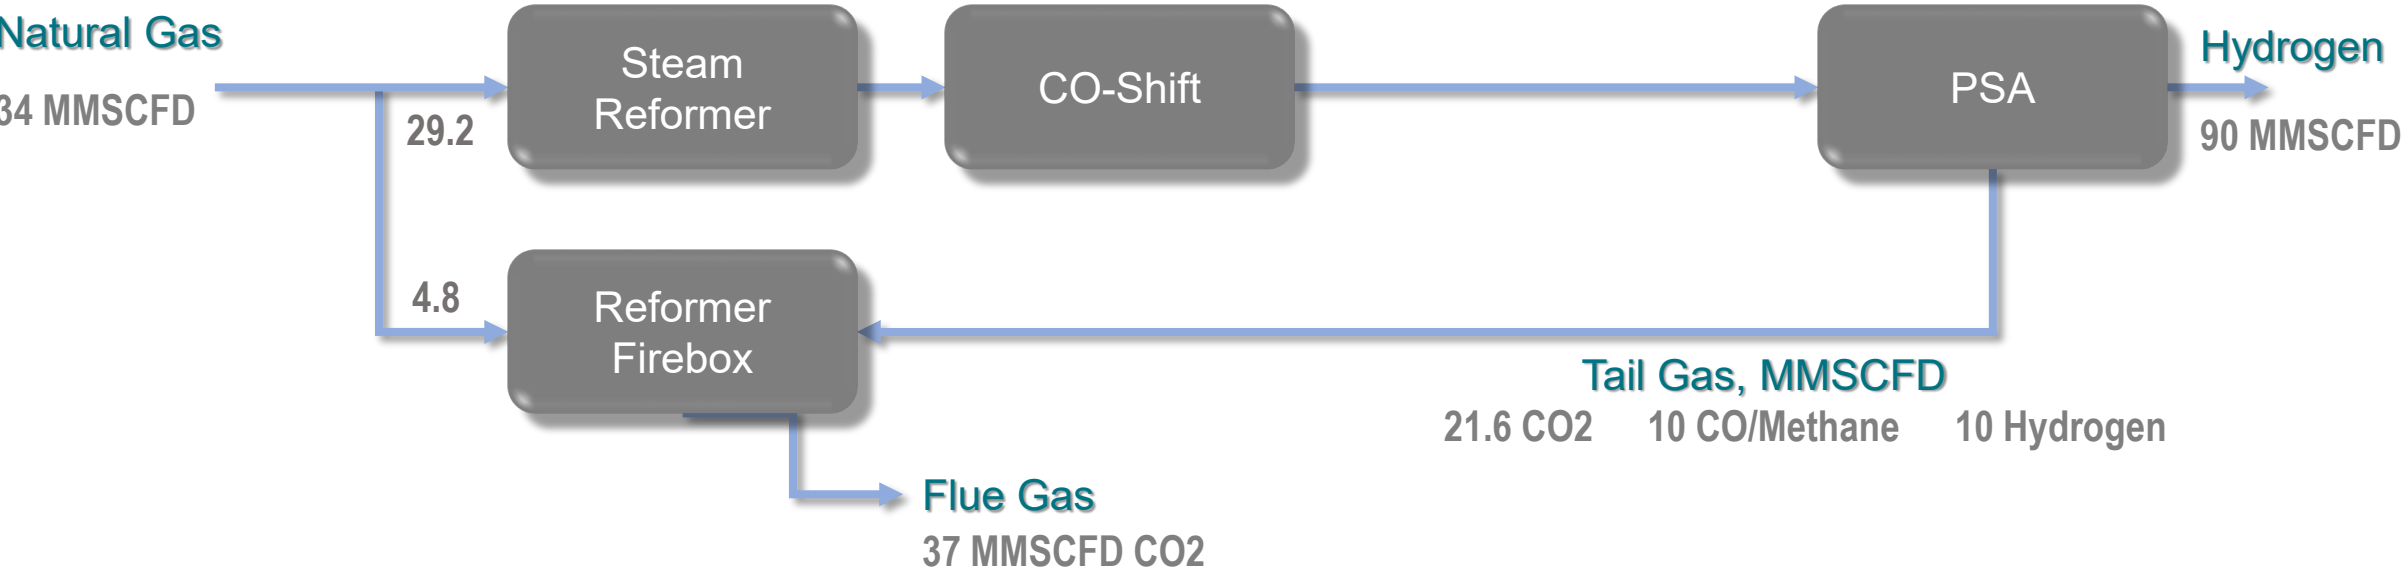

- Carbon capture costs vary with technology, but are only one piece of the total
- Reducing CO2 Capture costs by 50% affects the total cost by only 20%

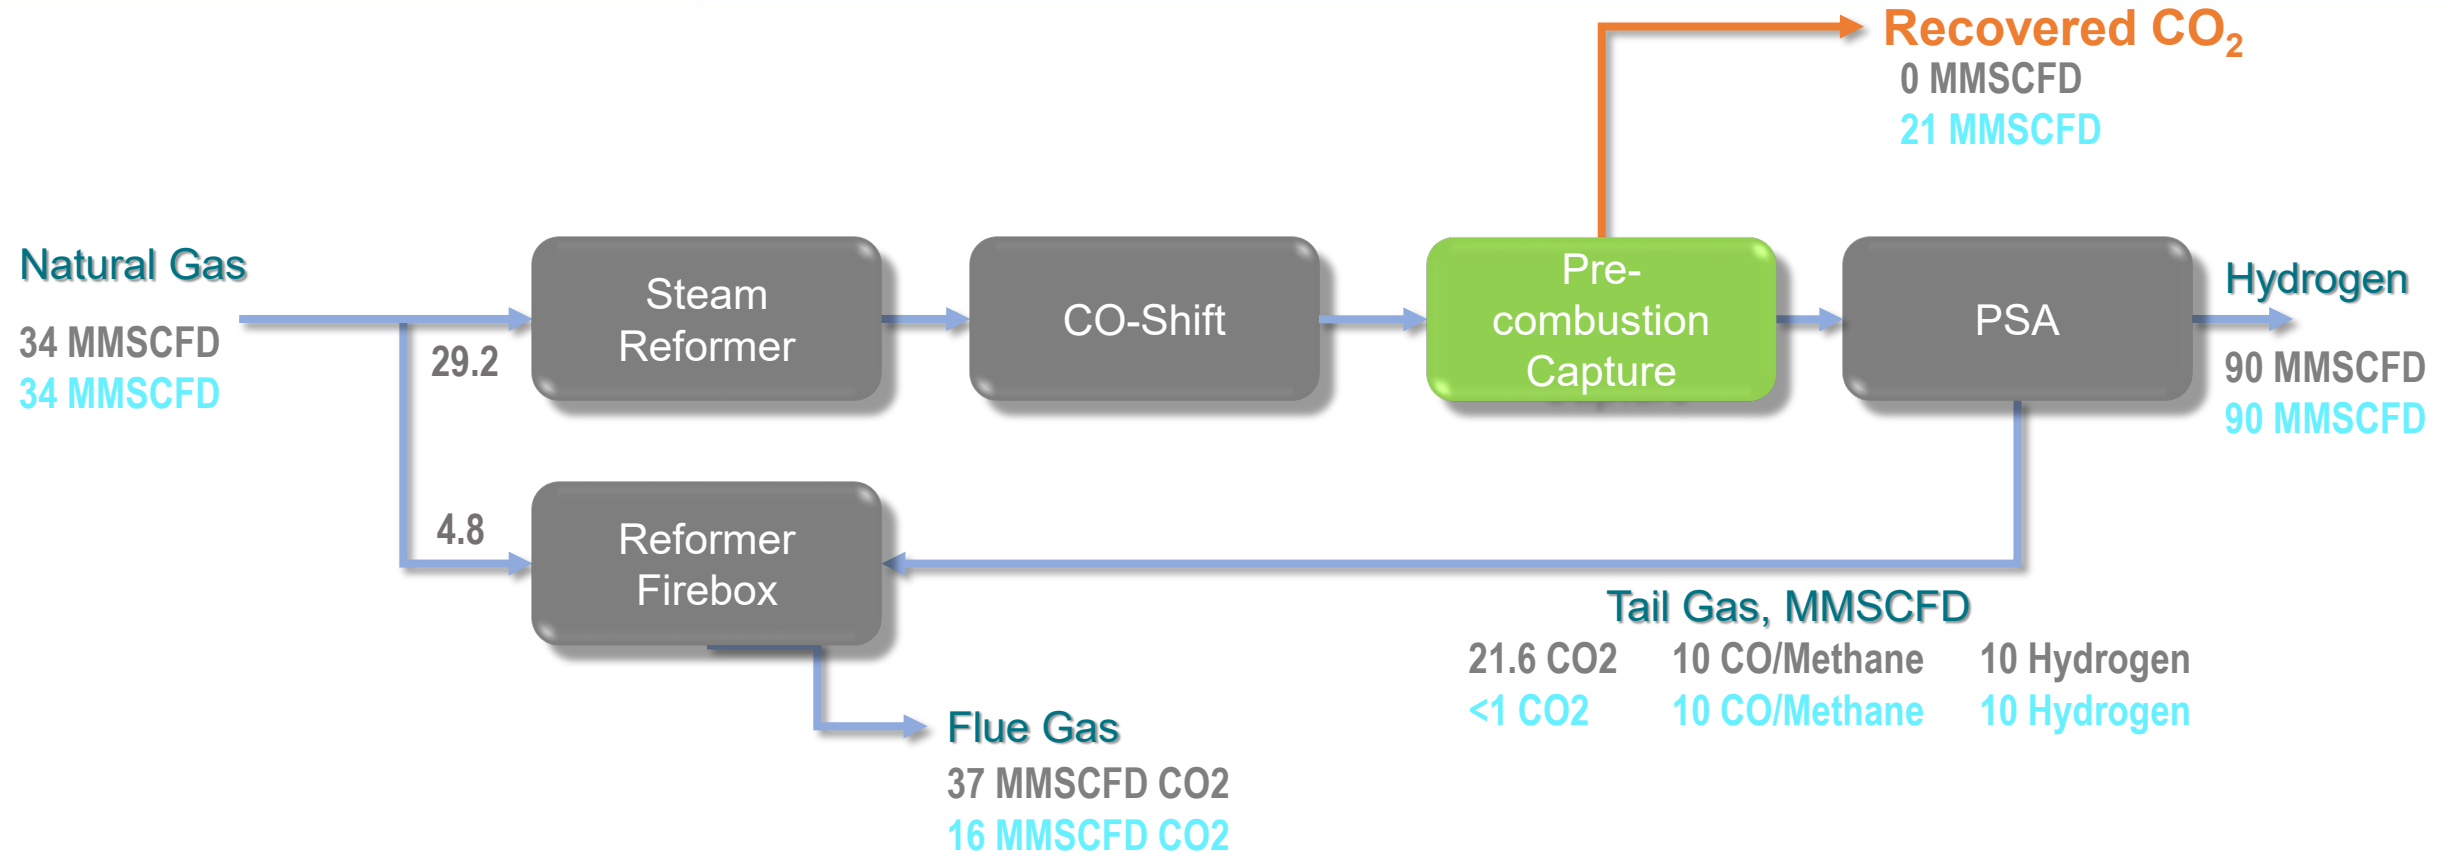

Incentives for Low Carbon Hydrogen

- Enhanced Oil Recovery: Varies, but perhaps \$35/MT
- US 45Q Incentives: \$35-50/MT
- Low Carbon Fuel Standard: Varies by destination, but can be \$200/MT for liquid fuel producers
- Current Cap and Trade: Varies by location, but ~\$20/MT
- Future regulation may significantly increase

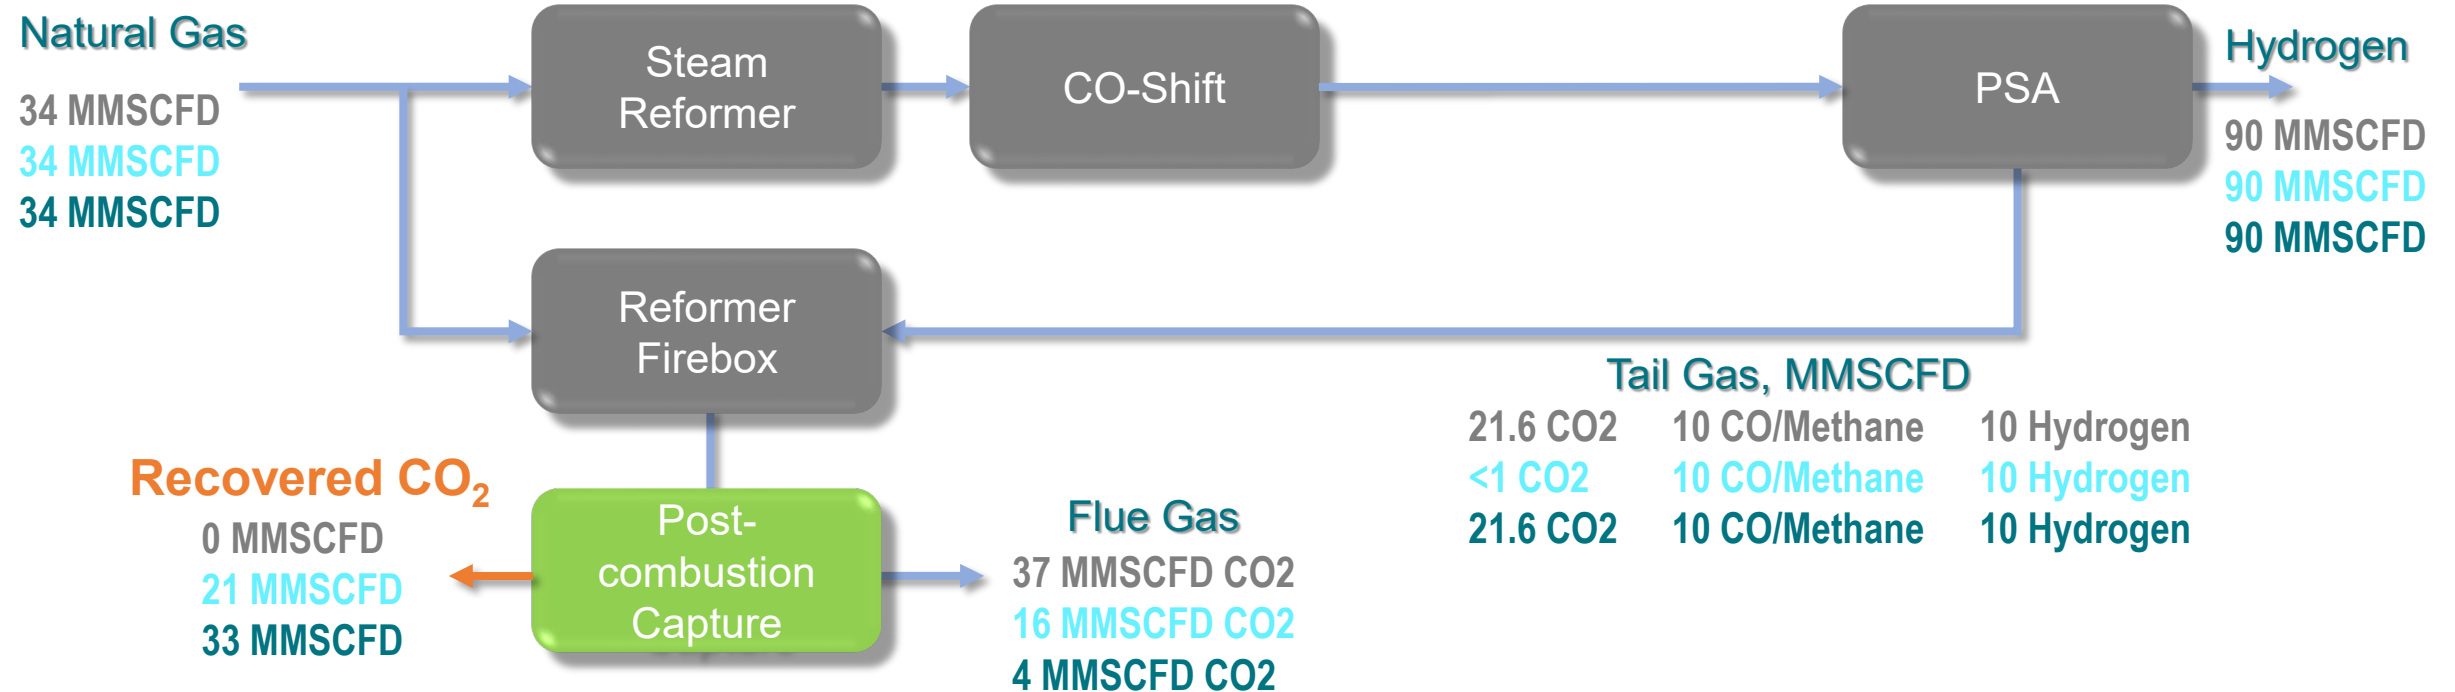

Modern SMR Hydrogen Plant

Precombustion SMR Carbon Capture (57% Direct Emissions Captured)

Postcombustion SMR Carbon Capture (90% Direct Emissions Captured)

Major Operating Costs

| | Precombustion Amine | Postcombustion Amine | Physical Solvent |
|--|---------------------|----------------------|------------------|
| Steam, MT/MT CO2 | 1.14 | 1.15 | 0 |
| Power, kWh/MT CO2 | 138 | 173 | 198 |
| Cost, \$/MT CO2 (\$5/1000 lb steam, \$0.05/kWh) | \$19.50 | \$21.30 | \$9.90 |

Amine utilities from actual operating facilities, public domain data, for relatively CO2 rich sources. Solvent utilities estimated. Steam and power costs will vary with facility

Physical Solvent for Carbon Capture

| | Physical Solvent | Amines |
|--|------------------------|-------------------------|
| Composition | Non-Hazardous | May be Hazardous |
| Metallurgy | Generally Carbon Steel | Stainless Steel |
| Solvent Degradation | Not a concern | Significant concern |
| Regeneration | Simple flashing | Steam-based regenerator |
| Solvent Maintenance/ Reclamation System | Not Required | Required |
| CO2 Captured | Highly concentrated | Highly concentrated |
| CO2 Capture Percentage | >90% | >90% |

Physical solvent based on Fluor Solvent

Other Routes to Blue Hydrogen

- Autothermal Reformer or POX with Carbon Capture
 - No reformer furnace loads to consider
- Adsorption
 - Vacuum Swing Adsorption by Air Products

How Green is Blue Hydrogen?

- A recent article (“How Green is Blue Hydrogen”, Howarth and Jacobson) has created recent news
- The premise that fugitive emissions is important to consider is valid, but the conclusion in the headlines needs to be considered critically

The image shows a screenshot of a news article header from the Houston Chronicle. At the top left is a hamburger menu icon. To its right is the Houston Chronicle logo, which consists of the word "HOUSTON" followed by a yellow star and the word "CHRONICLE". Below the logo is the article title: "'Blue hydrogen,' touted as clean natural gas product, may pollute more than coal, new research finds". Underneath the title is the author's name, "James Osborne", next to a small circular profile picture. Below the author's name is the date and time: "Aug. 13, 2021 | Updated: Aug. 13, 2021 11:50 a.m.". The entire snippet is set against a white background with a thin black border.

How Green is Blue Hydrogen?

- The following analysis is based on the IEAGHG 2017-02 report, which considers:
 - A full material balance of a modern SMR hydrogen plant, with the value of produced steam converted to electricity
 - A full material balance of a conservative postcombustion carbon capture facility, with steam and power generated from the SMR excess steam
- This analysis considers the full energy impact of the hydrogen plant and onsite carbon capture

How Green is Blue Hydrogen?

| | Howarth and Jacobson | Industry Experience |
|---------------------------|---|--|
| Energy for Carbon Capture | Separately produced without carbon capture, adds to emissions | Steam is a byproduct of SMR process and can be used to generate power |
| Energy Inputs for SMR | High level figure from literature | Rigorous material balance is 18% lower |
| Carbon Capture Rate | 65-85%. Low end from cycling power plant | $\geq 90\%$ in steady state operation. Cyclic operation will be lower, but many hydrogen plants are steady state |

Grey Hydrogen

| | Value used in Howarth and Jacobson | mol Methane per mol H2 Produced |
|----------------------|------------------------------------|---------------------------------|
| SMR Process | 0.875 mol Methane / MJ H2 | 0.250 |
| Fuel | 0.1814 MJ Energy / mol H2 | 0.206 |
| Electricity Required | Included above | |
| Total | | 0.456 |

First, convert the data from the article to moles to compare material balance data

Grey Hydrogen

Compare with rigorous material balance

Mol Methane / Mole H2 Produced

| | Howarth and Jacobson | IEAGHG 2017-02 Base Case (1) |
|----------------------|----------------------|------------------------------|
| SMR Process | 0.250 | 0.336 |
| Fuel | 0.207 | 0.059 |
| Electricity Required | Included above | -0.02 |
| Total | 0.456 | 0.376 |

Higher as some methane is unreacted and PSA sends some H2 to furnace

Exported steam converted to power. Power converted to methane using US average natural gas power plant

Net methane requirements 18% lower

Note 1: Converted from a natural gas basis to a pure methane basis by Fluor to place on the same basis as Howarth and Jacobson

Blue Hydrogen (Postcombustion) Material Balance

Mol Methane / Mole H2 Produced

| | Howarth and Jacobson Grey H2 | IEAGHG 2017-02 Base Case (Grey H2) | IEAGHG 2017-02 Case 3 (Blue H2) |
|----------------------|------------------------------|------------------------------------|---------------------------------|
| SMR Process | 0.250 | 0.336 | 0.336 |
| Fuel | 0.206 | 0.059 | 0.10 |
| Electricity Required | Included above | -0.02 | 0 |
| Total | 0.456 | 0.376 | 0.437 |

CO2 Emissions

Assume 3.5% Fugitive Emissions, 20 Year Life

| | Howarth and Jacobson | | IEAGHG 2017-02 | |
|--|----------------------|------|----------------|------|
| | Grey | Blue | Grey | Blue |
| Direct Emissions, mol CO2/mol H2 | 0.46 | 0.21 | 0.40 | 0.05 |
| Fugitive Emissions, mol CO2 Equiv/ mol H2 | 0.50 | 0.62 | 0.41 | 0.48 |
| Upstream Emissions | 0.03 | 0.04 | 0.03 | 0.03 |
| Total, mol CO2/mol H2 | 0.99 | 0.87 | 0.84 | 0.56 |
| Reduction | | 12% | | 33% |

CO2 Emissions

Assume 1.75% Fugitive Emissions, 20 Year Life

| | Howarth and Jacobson | | IEAGHG 2017-02 | |
|--|----------------------|------|----------------|------|
| | Grey | Blue | Grey | Blue |
| Direct Emissions, mol CO2/mol H2 | 0.46 | 0.21 | 0.40 | 0.05 |
| Fugitive Emissions, mol CO2 Equiv/ mol H2 | 0.25 | 0.31 | 0.21 | 0.24 |
| Upstream Emissions | 0.03 | 0.04 | 0.03 | 0.03 |
| Total, mol CO2/mol H2 | 0.74 | 0.57 | 0.63 | 0.32 |
| Reduction | | 24% | | 50% |

How Green is Blue Hydrogen?

- Fugitive emissions from natural gas add a “base load” of GHG emissions that carbon capture cannot adjust
- Assumptions of time horizon and fugitive methane emissions strongly affect GHG intensity of natural gas
- It is important to consider the full energy balance of hydrogen production and CO2 capture in the overall system
- For an existing facility, operating with carbon capture should always improve GHG emissions vs operating without

Low Carbon Hydrogen Use Cases

Retrofit of Existing Facilities

- Ability of a solution to integrate with existing facility is key
- Destination of CO₂ is important; carbon utilization can provide options if local storage not available

New Facilities with H₂ as a Feedstock

- May be able to adjust facility location and process for CO₂ capture and storage
- Energy source for hydrogen production affects product carbon intensity

New Facilities with H₂ as an Energy Source

- Energy source for hydrogen production is key
- Steady state vs intermittent energy production is a key variable for the process and its integration
